Separation of the variable is done when the differential equation can be written in the form of  $dy/dx = f(y)g(x)$  where  $f$  is the function of  $y$  only and  $g$  is the function of  $x$  only. Taking an initial condition we rewrite this problem as  $1/f(y)dy = g(x)dx$  and then integrate them from both sides. Also, check: Solve Separable Differential Equations ...

We use subfunctions and superfunctions to derive sufficient conditions for the existence of extremal solutions to initial value problems for ordinary differential equations with discontinuous and singular nonlinearities.

Asymptotic analysis is a branch of mathematical analysis that describes the limiting behavior of the function. This behavior appears when we study the solution of differential equations analytically. The recent work deals with a special class of third type of Painlevé differential equation (PV). Our aim is to find asymptotic, symmetric univalent solution of this class in a symmetric domain ...

and Minkowski problems as well as Nash's theorem), Yang-Mills fields, the wave equation and spectrum of the Laplacian, and problems on compact manifolds with boundary or complete non-compact manifolds. In addition, these lectures discuss only existence and uniqueness theorems, and ignore other more qualitative problems.

In the second part we study the asymptotic Dirichlet problem when  $M$  is the hyperbolic space  $\mathbb{H}^n$  and  $\Omega$  is the whole space. This part uses in an essential way the geometric structure of  $\mathbb{H}^n$  to construct special barriers which resemble the Scherk type solutions of the minimal surface PDE.

The combination of a differential equation and an initial condition (also known as a constraint) is called an initial value problem (abbreviated IVP). For differential equations involving higher derivatives, two or more constraints may be present.

In this article, we prove the existence and uniqueness of a solution for 2-dimensional time-fractional differential equations with classical and integral boundary conditions. We start by writing this problem in the operator form and we choose suitable spaces and norms. Then we establish prior estimates from which we deduce the uniqueness of the strong solution.

Types of differential equations. Basically, there are two types of differential equations; Ordinary Differential Equation (ODE) Ordinary differential equation involves a relation between one real variable which is independent say  $x$  and one dependent variable say  $y$  and sum of derivatives  $y'$ ,  $y''$ ,

$y'''' \dots$  with respect to the value of  $x$ .

2 Boundary Value Problems If the function  $f$  is smooth on  $[a;b]$ , the initial value problem  $y' = f(x;y)$ ,  $y(a)$  given, has a solution, and only one. Two-point boundary value problems are exemplified by the equation  $y'' + y = 0$  (1) with boundary conditions  $y(a)=A, y(b)=B$ . An important way to analyze such problems is to consider a family of solutions of ...
